

# 50 experiments from the FOIA files

Oct 1, 2026 · @'P

## How to use this list

Every idea traces to a declassified US government document, and every one is buildable from your kit plus at most a cheap sensor. Pick by number and I'll build the ones you choose.

- **Sources:** the CIA's FOIA reading room (CREST, including the STAR GATE / SRI / SAIC files), plus DIA, Army and Navy reports released under FOIA. Each item links its document.
- **Hardware assumed:** the PZ7020 FPGA (lock-in, coincidence counter, correlator), 2× Teensy 4.1, about 15 ESP32s, 3 GPS modules, CC1101s, the SX1262 kit, 6× MPU-6050, INA219s, the logic analyzer and the A1 mini. Extra parts come with rough prices.
- **Safety filter:** nothing that transmits above legal ISM power, exposes anyone to strong RF, high voltage or loud infrasound, or is aimed at other people. Self-tests with light, sound or biofeedback carry their warnings.
- **Evidence grade:** A = solid physics or a replicated result. B = reported in the documents but never properly re-tested. C = an extraordinary claim most scientists reject; worth running only blinded, with the analysis fixed in advance.

Each item gives the claim, the document, the build, and the result that would actually matter.

## Shortlist

One item cleared the "we have to rerun that" bar: #19, solar flares on Navy VLF. An Air Force study of 4,500+ flares found VLF signals peak 2.7 minutes after the X-ray peak, and your board can measure that lag on 8 stations at once. It is now built as `fpga/vlf_sid`. No psi item clears the bar on evidence; #32 and #34 are here because they are cheap and decisive.

| #  | Experiment                              | Why it made the list                                                                                       | Where it stands                                                                                                                                                                                                                                                                  |
|----|-----------------------------------------|------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 19 | Solar flares on Navy VLF                | Grade A physics with a published number to check: 2.7 min lag (2.1–3.4 by transmitter)                     | Built. Vivado 2026.1: exit 0, timing met (+6.3 ns), 17 % LUTs, 0.15 W. Simulation: 33/33 checks, every I/Q value bit-exact vs a reference model. Needs a loop antenna, a preamp and a 3.3 V USB-serial adapter; GPS optional                                                     |
| 24 | Do rocket launches ring the ionosphere? | Never replicated; the Navy saw it "very poorly in San Diego", and Vandenberg launches are ~350 km from you | Next up. Runs on the ELF logger you have, plus a large coil                                                                                                                                                                                                                      |
| 14 | EEG-gated sleep learning                | The one body item with modern support: meta-analysis $g = 0.29$                                            | Needs the EEG headband build                                                                                                                                                                                                                                                     |
| 32 | The decisive test SAIC never ran        | Proposed in 1995 to settle "push vs pick"; no record it was ever run                                       | Needs the FPGA TRNG (#36) first                                                                                                                                                                                                                                                  |
| 34 | Swann's steel-box run                   | About 40 runs settle the claim, the cheapest decisive test here                                            | A ~\$5 noise TRNG and a steel ammo can                                                                                                                                                                                                                                           |
| 2  | Torsion pendulum in a bell jar          | SRI reported 5:1 changes from 1 m with no statistics; a lock-in phase readout makes it a clean blind test  | Built Oct 1, v2 (not yet run on hardware): the bottle is cut to a sleeve that wedges on printed 45-degree cones (fits any 100-120 mm 2-liter), flat printed floor with a backlit window, ESP32-S3 camera tracker, logged sessions with exact stats, in freq-lab/torsion_pendulum |

| #  | Experiment                      | Why it made the list                                                                                           | Where it stands                                                                                                    |
|----|---------------------------------|----------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------|
| 6  | Being watched remotely          | SAIC got $p < 0.005$ over 48 sessions; the later meta-analysis shrank it to $d = 0.11$                         | Paused until there's a GSR sensor and a second person to watch. Plan: GSR amp on a Teensy plus the ESP32-S3 camera |
| 36 | Health-tested FPGA TRNG         | An auditable random target picker for every test here, the way SRI certified its generator; #32 needs it first | Queued (your pick). Runs on the Zynq board you have                                                                |
| 38 | Sonic boom and infrasound array | NASA logged about 800 booms from 0.1 Hz (1964); the same array would also hear the launches in #24             | Queued (your pick). 3-4 ESP32 nodes with SDP31 pressure sensors and GPS                                            |

Next for #19: wire a loop antenna and preamp to JM1-6/8, load `vlf_sid.bit`, then run `vlf_host.py scan` to see which stations you hear.

## SRI / SAIC lab experiments

The lab side of the remote-viewing program: real instruments, mostly one-subject pilots, almost none re-tested blind. Each build adds the control the original lacked.

| # | Experiment                              | What the file says                                                                                                                                          | Your build                                                                                                                                                                                            | Grade | Pick |
|---|-----------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|------|
| 1 | <a href="#">Gradiometer on/off test</a> | Swann sat 4 m from a superconducting gradiometer during random activity/rest periods: 42 events in activity periods vs 21 in rest, $p = 0.004$ (SRI, 1974). | Two FG-3+ fluxgates (~\$110) as a gradiometer; the FPGA times their pulse periods at 50 MHz; a third sensor on GPS time cancels common signals; an RNG sets the schedule and the analyst stays blind. | C     | ▼    |

| # | Experiment                                           | What the file says                                                                                                                                                                                                    | Your build                                                                                                                                                                                                                                       | Grade | Pick |
|---|------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|------|
| 2 | <a href="#">Torsion pendulum in a bell jar</a>       | Three 100 g balls on a metal fiber in a sealed bell jar, laser readout 1.5 m away: change-to-baseline "often 5:1" from 1 m and "typically 2:1" from 12 m. Randomized, but no statistics (SRI, 1974).                  | Printed rotor with steel balls in a sealed tube; LED or $\leq 1$ mW laser onto a line sensor (~\$15). The lock-in drives it gently at resonance, so any damping shows up as a phase shift. A 37 °C water-bottle "dummy person" tests convection. | C     | ▼    |
| 3 | <a href="#">Piezo strain gauges, "remote action"</a> | One of 5 people produced 11 events over 25 mV (noise 4 mV), none in ~30 h of controls. SRI's <a href="#">1987 follow-up</a> found "no evidence" and traced the pilot to an 8 Hz resonance.                            | Two piezo discs on masses in a grounded can with charge amps (\$15), both on the XADC at 195 kS/s. Veto channels on the coincidence counter: mic, IMU, fluxgate and a muon paddle (\$100).                                                       | C     | ▼    |
| 4 | <a href="#">Shielding audit: cage vs ELF</a>         | SRI's copper cage gave 120 dB against radio waves but only 68 dB against magnetic fields at 15 kHz, falling to 3 dB at 60 Hz, so it never blocked ELF (SRI, 1974; <a href="#">SRI, 1978</a> ).                        | Printed transmit and receive coils; the lock-in sweeps 10 Hz–100 kHz through copper mesh, aluminum, steel, mu-metal foil and a 30 cm tube of brine (~\$20 plus salt). Compare with skin-depth theory.                                            | A     | ▼    |
| 5 | <a href="#">Remote stimulus vs fake stimulus</a>     | A receiver's alpha phase shifted when a sender 40 m away saw flashes ( $Z = 1.99$ ), but blank "pseudo-stimuli" shifted it more ( $Z = 2.92$ ). SAIC's follow-ups were null (SRI, 1990; <a href="#">SAIC, 1993</a> ). | ADS1299 EEG (~\$50) on battery; an ESP32 screen as the sender; a photodiode and the EEG stamped by the FPGA on GPS time. Start with a 12 kΩ saline phantom to see whether the sender's electronics leak into the amplifier.                      | C     | ▼    |

| # | Experiment                                         | What the file says                                                                                                                                                                                                                                             | Your build                                                                                                                                                                                                                 | Grade | Pick |
|---|----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|------|
| 6 | <a href="#">Being watched remotely</a>             | Skin conductance changed when a remote observer watched on CCTV during 16 random 30 s periods out of 32: combined $p < 0.005$ over 48 sessions, effect size 0.36–0.44 (SAIC, 1994). Later meta-analysis: about $d = 0.11$ .                                    | GSR amp (~\$10) on a Teensy; the ESP32-S3 camera streams you to a friend whose screen blanks in control periods; the FPGA RNG sets the schedule, with its hash posted first. You are the only subject.                     | C     | ▼    |
| 7 | <a href="#">Target entropy or camera artifact?</a> | Session quality tracked the target photo's entropy gradient ( $p = 0.45$ , $n = 28$ ), but re-scanning the same photos dropped it to 0.30, not significant (SAIC, 1994).                                                                                       | Shoot 50 scenes on the ESP32-S3 camera and a phone at different settings, compute SAIC's measure on the Orange Pi, and check its stability across cameras before using it for anything.                                    | B     | ▼    |
| 8 | <a href="#">ESP teaching machine</a>               | A 4-choice machine with feedback: one subject hit 29.4% over 2,500 trials (chance 25%), $p = 3 \times 10^{-7}$ . SRI's own 1989 meta-analysis put forced-choice at $d = 0.05$ (SRI for NASA, 1975).                                                            | ESP32 box with 4 lit buttons; the FPGA TRNG picks each target and commits it by hash before the press; $10^9$ bits checked with the NIST tests.                                                                            | C     | ▼    |
| 9 | <a href="#">Geophysical station</a>                | SRI logged ionospheric disturbances, geomagnetic indices and ELF at 19 frequencies against session scores; "nine of ten" data sets had a disturbance on session day. SAIC later found $p = -0.05$ over ~1,000 trials (SRI, 1984; <a href="#">SAIC, 1993</a> ). | The VLF receiver from #19, a buried fluxgate for a local K-index, and GPS sidereal time. First measure how often disturbances happen on random days: near solar max it's most days, which makes "nine of ten" meaningless. | C     | ▼    |

## The body

The Monroe and Gateway papers make the most specific physiological claims in the files, and most of them can be checked with a \$50–250 EEG board. Run every body sensor on battery or through a USB isolator, keep audio under 60 dB, and use a sham track every time.

| #  | Experiment                                | What the file says                                                                                                                                                                                                                    | Your build                                                                                                                                                                                                                                                                                                                                            | Grade | Pick |
|----|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|------|
| 10 | <a href="#">Beat-locked EEG</a>           | Monroe told an Army Science Board panel that a 3–5 Hz binaural beat "synchronously drives" both hemispheres; the panel never checked because the lab was "being remodeled" (Army Science Board, 1983; <a href="#">Monroe paper</a> ). | The Teensy plays a 4 Hz beat binaurally, monaurally and not at all, in random order; two EXG front ends (~\$12 each) at C3/C4 feed the XADC; the FPGA lock-in uses the beat as its reference. A saline-sponge phantom rules out pickup from the headphones.                                                                                           | B     | ▼    |
| 11 | <a href="#">Gateway session polygraph</a> | The 1983 Army assessment says Hemi-Sync makes both hemispheres "equal in amplitude and frequency", holds you at "the threshold of sleep" and lowers blood pressure; one meditator held it "for over 15 minutes" (US Army, 1983).      | ADS1299 at F3/F4, C3/C4 and O1/O2 plus eye and muscle channels, a MAX30102 pulse sensor (\$5) and a BP cuff (\$30). Beats hidden in surf noise vs the same track without them, coded at random; faint probe tones you answer with a tap. Add the report's humming exercise and its 6.8–7.5 Hz body-micromotion claim on your ballistocardiograph rig. | B     | ▼    |
| 12 | <a href="#">Holding sleep stages</a>      | Monroe claimed beats can "hold the subject into any of the various stages of sleep", and a beta signal after REM wakes you without grogginess (Monroe Institute bulletin, undated).                                                   | Frontal EEG/EOG headband, IMU and sleep earbuds. Nights randomly get a 2 Hz beat from stage N2 or a no-beat track; wake-ups get a beta ramp, a plain ramp or an alarm. Stage the night with YASA; reaction-time test on the AMOLED watch.                                                                                                             | B     | ▼    |
| 13 | <a href="#">REM-cued lucid dreams</a>     | A mask giving "one or two flashes per second" during REM "enhanced the frequency of lucid dreaming"; the appended LaBerge study logged 35 lucid dreams, 32 in REM, verified by eye signals (SAIC draft protocol, 1991).               | Printed mask with 2-channel EOG, an IMU and dim red LEDs on an ESP32-S3. Nights randomly get REM flashes, REM audio, or flashes in non-REM sleep as an active sham; score the agreed left-right eye signals.                                                                                                                                          | B     | ▼    |

| #  | Experiment                                         | What the file says                                                                                                                                                                                                                                 | Your build                                                                                                                                                                                                                                                                     | Grade | Pick |

|----|------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|------|
| 29 | <a href="#">Dermo-optics: measure the cues first</a> | A Soviet subject named hidden colors 113 times in 200 (chance 50) and 77 times from "a few meters"; Chinese "ear reading" claimed over 80% (DIA, 1978; <a href="#">SRI for DIA, 1982</a> ).                                 | First measure the physical cues: an MLX90640 thermal camera ( <del>\$60</del> ) and a TSL2591 light sensor (\$7) check temperature differences and light leaks between colored cards. Then 200 blind trials with cards from a dark box at even temperature. | C     | ▼    |
| 30 | <a href="#">Brownian motion and "mind power"</a>     | Beijing University reported that the spread of Brownian motion changed 24% under "mind power", significant only at $P < 10\%$ (qigong conference abstracts, 1988). Stokes-Einstein says 24% would need 15–20 °C of warming. | A 3D-printed OpenFlexure-style microscope (~\$60) on the Orange Pi filming 1 µm beads in a sealed cell, a thermistor on the slide, drift-corrected tracking in blind RNG blocks.                                                                            | C     | ▼    |

## Randomness

The mainstream verdict is that mind-over-RNG effects aren't real: PEAR's [three-lab replication](#) came out at  $Z = 0.6$ , and a [12,571-person test](#) favored no effect 10 to 1. These builds are designed so a null still tells you something, and the FPGA gives you a cleaner random source and better timing than any of the originals had.

| #  | Experiment                                        | What the file says                                                                                                                                                                                                                                                          | Your build                                                                                                                                                                                                                                                      | Grade | Pick |

| 32 | <a href="#">The decisive test SAIC never ran</a> | If minds push random generators, the effect should grow with bits per trial; if they only pick lucky moments ("decision augmentation"), it shouldn't. Across 128 studies it didn't grow. SAIC proposed 1,500 runs at $10^2$ vs $10^4$ bits to settle it, and there's no record anyone ran it (SAIC, 1995). | Same TRNG; each press emits a hidden, randomly chosen $10^2$ , $10^4$ or $10^6$ bits inside one fixed 10 ms window, so timing is identical across sizes. 500 runs per size; a flat result caps any "push" near $7 \times 10^{-5}$ per bit.                               | C     | ▼    |
| 33 | <a href="#">Schmidt's four-lamp machine</a>      | Helmut Schmidt's strontium-90 machine at Boeing: 3 subjects, 63,066 trials, 26.1% hits vs 25%, $p < 2 \times 10^{-9}$ ; critics noted no control for short-run bias (journal review kept in the STAR GATE files, 1987).                                                                                    | An SBM-20 Geiger board (~\$30) into a Teensy; each pulse latches the 600 MHz cycle counter mod 4 to pick the lamp, and every pulse between trials is logged as a control. About 10,000 trials for 80% power. Background radiation or a license-exempt check source only. | C     | ▼    |
| 34 | <a href="#">Swann's steel-box run</a>            | A 50 bit/s noise generator, 29 runs of 1,000: Swann averaged 493 vs 500 expected, $p = .011$ ; controls averaged 499.7. His last 10 runs, behind "two double steel walls", averaged 491.8 (Maimonides Medical Center, 1976).                                                                               | A battery avalanche-noise TRNG (~\$5) and a Teensy in a grounded steel ammo can in another room; the TRNG secretly sets the lid open or closed for each run. The claimed shift is so large that ~40 runs settle it, the cheapest decisive test on this list.             | C     | ▼    |
| 35 | <a href="#">Two-site, three-source network</a>   | SRI and Syracuse designed beta-decay, noise-diode and pseudo-random generators at two sites, but "no experimental data were recorded" (SRI, 1986). Never run.                                                                                                                                              | Each station: an avalanche TRNG, an SBM-20 and a PRNG on GPS PPS; correlate 1-second bit sums between stations. One day of data flags any shared artifact (mains, HVAC, RF) above $r = 0.01$ .                                                                           | C     | ▼    |

| #  | Experiment                              | What the file says                                                                                                                                                                                                     | Your build                                                                                                                                                                                                                                                                             | Grade | Pick     |

| 43 | <a href="#">Electrostatic "PK table"</a>                | Soviet researchers "recorded fields of 10,000 volts/centimeter" near a target object, pulsing with breathing, heartbeat and alpha rhythm; Kulagina could never move an electroscope (DIA, 1975; <a href="#">Adamenko, CIA translation</a> ).                                              | A 50 cm acrylic top, a 3D-printed field mill (\$20), an electrometer (\$10), ECG (~\$10) and a breathing belt; the FPGA correlator checks whether the field really tracks heartbeat and breath. RNG-scheduled effort and rest, plus empty-room shams.                        | C     | ▼    |
| 44 | <a href="#">Pavlita's sealed rotor and "generators"</a> | Foil "mounted in a sealed container" started and stopped on command, and Pavlita's "generators" worked "as a result of their form" through glass, water and metal. After two years the testers judged it "not sufficient for a scientific paper" (DIA, 1978; <a href="#">DIA, 1975</a> ). | A foil vane on fine tungsten fiber in a sealed jar (~\$25), with an LED and split-photodiode readout through the lock-in; shields added one at a time (glass, water jacket, grounded copper). A servo places RNG-chosen "generators", printed pyramids and equal-mass shams. | C     | ▼    |

| #  | Experiment                                      | What the file says                                                                                                                                                                                                                                | Your build                                                                                                                                                                                                                        | Grade | Pick |
|----|-------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|------|
| 45 | <a href="#">Kulagina's pendulum, GPS-timed</a>  | Kulagina moved "clock pendulums" but nothing in a vacuum; Chinese researchers recorded watch hands moved by "exceptional" subjects (DIA, 1972; <a href="#">SRI for DIA, 1982</a> ).                                                               | A 25 cm brass pendulum in a sealed case with an IR light gate (~\$2); the FPGA stamps every swing at 20 ns against GPS ( $2 \times 10^{-8}$ per swing), while IMU tilt, thermistors and a field probe log the ordinary causes.    | C     | ▼    |
| 46 | <a href="#">Qigong vs a Geiger counter</a>      | Over 200 people tried to change Geiger counts with a palm 5 cm from the tube, and the abstract says "the emitted qi can change the counts" (qigong conference abstracts, 1988).                                                                   | A J305 or SBM-20 kit (~\$35); the FPGA stamps every pulse on GPS time; a 34 °C water glove with ~1.5 g of salt substitute matches a hand's natural potassium-40. Randomized palm, sham and empty blocks.                          | C     | ▼    |
| 47 | <a href="#">Flask heating: qi or hand heat?</a> | Solvent flasks warmed under qi and the authors called it "not a thermal current"; a Soviet lab in a DIA translation says a hand radiates about 100 mW, felt from 20–30 cm (qigong conference, 1988; <a href="#">DIA translation, 1990</a> ).      | Two water flasks with thermistors in an AC bridge on the lock-in (better than 1 mK); barriers of glass, plastic film and foil one at a time; a heated 34 °C glove as the phantom hand.                                            | C     | ▼    |
| 48 | <a href="#">Dowsing and magnet polarity</a>     | Estimates of "sensitive" people ran from 3% to 20–30%, with magnetic fields said to affect dowsing; Chinese subjects reportedly told magnet poles apart; in SRI's lab search, 8 of 36 people beat chance (DIA, 1978; <a href="#">SRI, 1986</a> ). | MPU-6050s on L-rods; RNG-driven solenoid valves send water down 1 of 10 hose runs; a servo flips a magnet under your palm on every trial so its sound gives nothing away. The Munich barn study, re-analyzed, came out at chance. | C     | ▼    |

| #  | Experiment                                 | What the file says                                                                                                                                                                                                                                                                | Your build                                                                                                                                                                                                                                                                            | Grade | Pick |
|----|--------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------|------|
| 49 | <a href="#">Plant "primary perception"</a> | Backster said a plant's polygraph trace jumped the instant he decided to burn it, and DIA reported a Soviet follow-up with hypnotized subjects. Horowitz found nothing in 60 trials ( <i>Science</i> , 1975) (newspaper clipping in CIA files, 1972; <a href="#">DIA, 1978</a> ). | Ag/AgCl electrodes with an INA333 and ADS1256 on a Teensy (~\$30); the lock-in tracks leaf impedance at 1 kHz without Backster's drift; RNG-scheduled "intent" periods stamped on GPS time; tilting the pot is the positive control.                                                  | C     | ▼    |
| 50 | <a href="#">"Treated water"</a>            | Qi sent from 7 km to about 1,900 km away reportedly put a large unknown peak in laser-Raman spectra of tap water, fading within an hour (Collected Works on Qigong Science, CIA files).                                                                                           | One bottle split into 8 sealed, coded vials, with the RNG picking 4 to "treat"; the lock-in sweeps a 4-electrode cell from 10 Hz to 100 kHz with 24-bit temperature logging, since conductivity moves about 2% per °C. (No Raman: it needs a laser above the safety limit used here.) | C     | ▼    |

## Left out on purpose

- **Microwave hearing, acoustic and "psychotronic" weapons:** the files cover them, but any build would mean exposing someone to RF or sound at harmful levels.
- **Electrosleep and brain stimulation (CES, tDCS):** the 1972 DIA report describes Soviet electrosleep; nothing here passes current through the body, and a 2018 review found the evidence for insomnia insufficient anyway.
- **Kirlian photography:** it needs high voltage, DIA's own sources say the images track moisture, and a [1972 CIA test](#) on plants found no differences.
- **Anything done to other people without their knowledge, jamming, and transmitting above ISM limits.**
- **Torsion fields:** the only US-held [document](#) reports a big Soviet budget and an Academy verdict of "pseudoscientific", with nothing measurable to test.
- **Spottiswoode's sidereal-time effect and SAIC's "presponse" work:** both are later journal papers, not in the released files.

## Sources

cia.gov blocks automated reading, so these were read through The Black Vault and Internet Archive copies filed under the same CIA document numbers; search a title or number at [cia.gov/readingroom](http://cia.gov/readingroom) for the official page. The numbers behind the shortlist (#2, #9, #19, #24, #34) were re-checked directly against these copies.
